

Classification Using Bayesian Logistic Regression:

Diabetes in Pima Indian Women

Presented by

Prasenjit Kapat

Outline

- Objectives and Data description
- Model Setup and choice of priors
- Analysis with Gaussian priors
- Analysis with Laplacian priors
- Conclusions

Objectives

- Classification problem from a bayesian perspective.
- Do not intend to focus on model selection or interpretation.
- Effects on the prediction error rate for different choices of prior for the parameters in the logistic regression model.

Data Description

- Data : Pima Indian Women Diabetes data
- A population of women who were at least 21 years old of Pima Indian heritage and living near Phoenix were chosen. They were tested for diabetes.
- The variables in our model were:
 - npreg : number of pregnancies
 - glu : plasma glucose concentration
 - bp : diastolic blood pressure (mm Hg)
 - skin : triceps skin fold thickness (mm)
 - bmi : body mass index kg/m^2
 - ped : diabetes pedigree function
 - age : Age (years)
 - response : Yes or No for diabetic according to WHO criteria.
- Total 532 instances of which 200 are in training set.

$$y_i | p_i \sim \text{Bernoulli}(p_i)$$

and assume

$$\text{logit}(p_i) = \log \left[\frac{p_i}{1 - p_i} \right] = \mathbf{x}_i^T \boldsymbol{\beta}$$

Choice of Priors

- Zellner's g-prior: $p(\boldsymbol{\beta}) \sim N(\boldsymbol{\beta}_0, g \times (\mathbf{X}^T \mathbf{X})^{-1})$
- Jeffrey's Prior : $p(\boldsymbol{\beta}) \propto [\det(\mathbf{X}^T \mathbf{W} \mathbf{V}(\boldsymbol{\beta}) \Delta^2(\boldsymbol{\beta}) \mathbf{X})]^{1/2}$
- Gaussian prior: $p(\boldsymbol{\beta}) \sim N(\boldsymbol{\beta}_0, \boldsymbol{\Sigma}_0)$
- Laplacian prior: $p(\beta_j | \lambda_j) = \frac{\lambda_j}{2} e^{-\lambda_j |\beta_j|}$

Analysis with Gaussian Prior

- $p(\boldsymbol{\beta}) \sim N(\boldsymbol{\beta}_0, \boldsymbol{\Sigma}_0)$
- We use empirical Bayesian approach to estimate $\boldsymbol{\beta}_0$ and $\boldsymbol{\Sigma}_0$ from the data;
- Based on the derived prior distribution, we obtain the posterior distribution of the regression parameters by MCMC approach;
- Based on the posterior distribution, prediction of the binary response will be made using two prediction rules, and relevant measures of prediction error will be calculated.

- Predict the presence of diabetes based on the posterior distribution:
 - i) For each $q_i^{(j)}$, we draw a $y_i^{(j)} \sim \text{Bernoulli}(q_i^{(j)})$, and let $y_i^{pre} = 1$ if the number of $y_i^{(j)}$'s equal to 1 is bigger than or equal to the number of $y_i^{(j)}$'s equal to 0, i.e. the proportion of $y_i^{(j)}$'s equal to 1 exceeds $1/2$, otherwise let $y_i^{pre} = 0$. We will refer to this prediction rule as rule i);
 - ii) Let $y_i^{pre} = 1$ if the median of the $q_i^{(j)}$'s is bigger than or equal to $1/2$, otherwise set $y_i^{pre} = 0$. We will refer to this prediction rule as rule ii).

- Optimization based approach: minimise $-l(\boldsymbol{\beta})$ to obtain the *MAP* estimator.
- Initial prior: $[\beta_j | \tau_j] \sim N(0, \tau_j)$
- prior on hyperparameters: $[\tau_j | \gamma_j] \sim \text{Exp}(\frac{1}{2} \gamma_j)$
- integrating out τ_j , we have $[\beta_j | \lambda_j] \sim \text{DE}(0, \lambda_j)$
- posterior negative-log-density of $\boldsymbol{\beta}$ is given by,

$$\begin{aligned}
 -l(\boldsymbol{\beta}) = & \left[\sum_{i=1}^n \log (1 + \exp\{-(\beta_0 + \mathbf{x}'\boldsymbol{\beta})y_i\}) \right] \\
 & + \sum_{j=0}^{d-1} (\log 2 - \log \lambda_j + \lambda_j |\beta_j|)
 \end{aligned}$$

Our Results

Laplace Prior Analysis

| Prior mean $\beta = 0$ | | | Prior mean $\beta = \hat{\beta}_{mle}$ | | | Prior mean $\beta = \hat{\beta}_{post\ mean}$ | | |
|---------------------------|--------------------|-------------------|---|--------------------|-------------------|--|--------------------|-------------------|
| prior variance | training error (%) | testing error (%) | prior variance | training error (%) | testing error (%) | prior variance | training error (%) | testing error (%) |
| ∞ | 28.00 | 29.82 | ∞ | 21.50 | 20.48 | ∞ | 23.00 | 26.81 |
| 10 | 22.00 | 21.99 | 10 | 21.50 | 20.48 | 10 | 21.50 | 19.88 |
| 100 | 21.50 | 19.56 | $100 \hat{\sigma}_{mle}^2$ | 21.50 | 20.48 | $100 \hat{\sigma}_p^2$ | 21.50 | 19.58 |
| | | | $\hat{\sigma}_{mle}^2$ | 21.50 | 20.48 | $\hat{\sigma}_p^2$ | 20.50 | 20.78 |

Previous Results for this data (D. Michie, D.J. Spiegelhalter, and C.C. Taylor (1994), p158).

Conclusions

- Analysis using both types of prior families gives similar results.
- The error rates obtained using the two prediction rules in Gaussian prior analysis are close.
- For Laplacian prior, prior of mean of $\beta = 0$ and prior variance of 100 yield the best testing error percentage.
- Bayesian analysis methods give lower error rates than the previously studied learning methods.
